Dear all,

in the SCTP use case working group we recently discussed about borders of stations and their representation in railML 3.x.

There are several candidates for implementation:

- * a dedicated <border> element
- * evaluate (linear or area) location of <operationalPoint>
- * topology-based aggregation of <netElement>

But before we think about the specific implementation, let me first ask you, dear community, whether you need to distinguish between "in-station" and "outside-of-station" and - if needed - which attributes do you expect the border to have?

As usual, any feedback is highly appreciated...

Best regards
Christian
